October 10, 2012

THIS IS A DRAFT. The package is not complete.

Contents

1 Introduction

The `networkDynamic` package provides support for a simple family of dynamic extensions to the `network (?)` class; these are currently accomplished via the standard `network` attribute functionality (and hence the resulting objects are still compatible with all conventional routines), but greatly facilitate the practical storage and utilization of dynamic network data. The dynamic extensions are motivated in part by the need to have a consistent data format for exchanging data, storing the inputs and outputs to relational event models, statistical estimation and simulation tools such as `ergm (?)` and `stergm`, and dynamic visualizations.

The key features of the package provide basic utilities for working with networks in which:

- Vertices have ‘activity’ or ‘existence’ status that changes over time (they enter or leave the network)
- Edges which appear and disappear over time
- Arbitrary attribute values attached to vertices and edges that change over time
- Meta-level attributes of the network which change over time

- Both continuous and discrete time models are supported, and it is possible to effectively blend multiple temporal representations in the same object

In addition, the package is primarily oriented towards handling the dynamic network data inputs and outputs to network statistical estimation and simulation tools like **statnet** and **stergm**. This document will provide a quick overview and use demonstrations for some of the key features. We assume that the reader is already familiar with the use and features of the **network** package.

Note: Although **networkDynamic** shares some of the goals (and authors) of the experimental and quite confusable **dynamicNetwork** package (?), they are incompatible.

2 How to start and end relationships easily

A very quick condensed example of starting and ending edges to show why it is useful and some of the alternate syntax options.

2.1 Activating edges

The standard assumption in the **network** package and most sociomatrix representations of networks is that an edge between two vertices is either present or absent. However, many of the phenomena that we wish to describe with networks are dynamic rather than static processes, having a set of edges which change over time. In some situations the edge connecting a dyad may break and reform multiple times as a relationship is ended and re-established. The **networkDynamic** package adds the concept of ‘activation spells’ for each element of a **network** object. Edges are considered to be present in a network when they are active, and treated as absent during periods of inactivity. After a relationship has been defined using the normal syntax or network conversion utilities, it can be explicitly activated for a specific time period using the **activate.edges** methods. Alternatively, edges can be added and activated simultaneously with the **add.edges.active** helper function.

```
> library(networkDynamic)           # load the dynamic extensions
> triangle <- network.initialize(3)  # create a toy network
> add.edge(triangle,1,2)             # add an edge between vertices 1 and 2
> add.edge(triangle,2,3)             # add a more edges
> activate.edges(triangle,at=1)      # turn on all edges at time 1 only
> activate.edges(triangle,onset=2, terminus=3,
+               e=get.edgeIDs(triangle,v=1,alter=2))
> add.edges.active(triangle,onset=4, length=2,tail=3,head=1)
> class(triangle)

[1] "networkDynamic" "network"
```

The **onset** and **terminus** parameters give the starting and ending point for the activation period (more on this and the **at** syntax later). When a network

object has dynamic elements added, it also gains the `networkDynamic` class, so it is both a `network` and `networkDynamic` object. Notice that the method refers to the relationship using the `e` argument to specify the ids of the edges to activate. To be safe, we are looking up the ids using the `get.edgeIDs` method with the `v` and `alter` arguments indicating the ids of the vertices involved in the edge. After the activity spells have been defined for a network, it is possible to extract views of the network at arbitrary points in time using the `network.extract` function in order to calculate traditional graph statistics.

2.2 Extracting a network

```
> degree<-function(x){as.vector(rowSums(as.matrix(x))
+                               +colSums(as.matrix(x)))} # handmade degree function
> degree(triangle) # degree of each vertex, ignoring time
[1] 2 2 2
> degree(network.extract(triangle,at=0))
[1] 0 0 0
> degree(network.extract(triangle,at=1)) # just look at t=1
[1] 1 2 1
> degree(network.extract(triangle,at=2))
[1] 1 1 0
> degree(network.extract(triangle,at=5))
[1] 1 0 1
> degree(network.extract(triangle,at=10))
[1] 0 0 0
```

At time 1, the vertex degrees match what would be expected for the ‘timeless’ network, but for the other time points the degrees are quite different. When the network was sampled outside of the defined time range (at 0 and 10) it returned degrees of 0, suggesting that no edges are present at all. It may be helpful to plot the networks to help understand what is going on. Figure ?? (page ??) shows the result of the standard plot command (`plot.network.default`) for the triangle, as well as plots of the network at specific time points.

```
> par(mfrow=c(2,2)) #show multiple plots
> plot(triangle,main='ignoring dynamics',displaylabels=T)
> plot(network.extract(
+   triangle,onset=1,terminus=2),main='at time 1',displaylabels=T)
> plot(network.extract(
+   triangle,onset=2,terminus=3),main='at time 2',displaylabels=T)
> plot(network.extract(
+   triangle,onset=5,terminus=6),main='at time 5',displaylabels=T)
```

ignoring dynamics

at time 5

Figure 1: Network plot of our trivial triangle network

3 Birth, Death, Reincarnation and other ways for vertices to enter and leave networks

3.1 Activating vertices

Many network models need the ability to specify activity spells for vertices in order to account for changes in the population due to ‘vital dynamics’ (births and deaths) or other types of entrances and exists from the sample population. In `networkDynamic` activity spells for a vertex can be specified using the `activate.vertices` methods. Like edges, vertices can have multiple spells of activity. If we build on the triangle example:

```
> activate.vertices(triangle,onset=1,terminus=5,v=1)
> activate.vertices(triangle,onset=1,terminus=10,v=2)
> activate.vertices(triangle,onset=4,terminus=10,v=3)
> network.size(network.extract(triangle,at=1)) # how big is it?
```

```
[1] 2
```

```
> network.size(network.extract(triangle,at=4))
```

```
[1] 3
```

```
> network.size(network.extract(triangle,at=5))
```

```
[1] 2
```

Using the `network.size` function on extracted networks shows us that specifying the activity ranges has effectively changed the sizes (and corresponding vertex indices, more on that later) of the network. Notice also that we’ve created contradictions in the definition of this hand-made network, for example stating that vertex 3 isn’t active until time 4 when earlier we said that there were ties between all nodes at time 1. The package does not prohibit these kinds of paradoxes, but it does provide a utility to check for them.

```
> network.dynamic.check(triangle)
```

Edges were found active where the endpoints where not in edge(s) 2 3.

```
$vertex.checks
```

```
[1] TRUE TRUE TRUE
```

```
$edge.checks
```

```
[1] TRUE TRUE TRUE
```

```
$dyad.checks
```

```
[1] TRUE FALSE FALSE
```

3.2 Deactivating elements

In this case, we can resolve the contradictions by explicitly deactivating the edges involving vertex 3:

```
> deactivate.edges(triangle,onset=1,terminus=4,  
+                 e=get.edgeIDs(triangle,v=3,neighborhood="combined"))  
> network.dynamic.check(triangle)
```

Edges were found active where the endpoints where not in edge(s) 3.

```
$vertex.checks  
[1] TRUE TRUE TRUE
```

```
$edge.checks  
[1] TRUE TRUE TRUE
```

```
$dyad.checks  
[1] TRUE TRUE FALSE
```

The deactivation methods for vertices, `deactivate.vertices`, works the same way, but it accepts a `v=` parameter to indicate which vertices should be modified instead of the `e=` parameter.

4 ‘Spells’: the magic under the hood

In which we provide a brief glimpse into the underlying data structures.

There are many possible ways of representing change in an edgeset over time. Several of the most commonly used are:

- A series of networks or network matrices representing the state of the network at sequential time points
- An initial network and a list of edge toggles representing changes to the network at specific time points
- A collection of ‘spell’ intervals giving the onset and termination times of each element in the network

This package uses the spell representation, and stores the spells as perfectly normal but specially named **active** attributes on the network. These attributes are a 2-column spell matrix in which the first column gives the onset, the second the terminus, and each row defines an additional activity spell for the network element. For more information, `?activity.attribute`. As an example, to peek at the spells defined for the vertices:

```
> get.vertex.activity(triangle) # vertex spells
```

```

[[1]]
      [,1] [,2]
[1,]     1     5

[[2]]
      [,1] [,2]
[1,]     1    10

[[3]]
      [,1] [,2]
[1,]     4    10

> get.edge.activity(triangle) # edge spells

[[1]]
      [,1] [,2]
[1,]     1     1
[2,]     2     3

[[2]]
      [,1] [,2]
[1,]  Inf  Inf

[[3]]
      [,1] [,2]
[1,]     4     6

```

Notice that the first edge has a 2-spell matrix where the first spell extends from time 1 to time 1 (a zero-duration or instantaneous spell), and the second from time 2 to time 3 (a ‘unit length’ spell. More on this below). The third edge has the interesting special spell `c(Inf, Inf)` defined to mean ‘never active’ which was produced when we deleted the activity associated with the 3rd edge.

Within this package, spells are assumed to be ‘right-open’ intervals, meaning that the spell includes its lower bound but not its upper bound. For example, the spell `[2,3)` covers the range between $t \geq 2$ and $t < 3$. Another way of thinking of it is that terminus=‘until’, the spell ranges from 2 until 3, but does not include 3.

Although it would certainly be possible to directly modify the spells stored in the `active` attributes, it is much safer to use the various `activate.` and `deactivate` methods to ensure that the spell matrix remains in a correctly defined state. The goal of this package is to make it so that it rarely necessary to work with spells, or even worry very much about the underlying data structures. It should be possible to use the provided utilities to convert between the various representations of dynamic networks. However, even if the details of data structure can be ignored, it is still important to be very clear about the underlying temporal model of the network you are working with.

5 Differences between Discrete and Continuous data

Its 2 am on Tuesday. Do you know what your temporal model is? Does 2am mean 2:00 am, or from 2:00 to 2:59:59? And other existential questions. The differences between `at` and `onset`, `terminus` syntax.

There are two different approaches to representing time when measuring something.

5.1 You might be discrete if...

The ‘discrete’ model thinks of time as equal chunks, ticks, discrete steps, or panels. To measure something we count up the value of interest for that chunk. Time is a series of integers. We can refer to the 1st step, the 365th step, but there is no concept of ordering of events within steps and we can’t have fractional steps. A discrete time simulation can never move its clock forward by half-a-tick. As long as the steps can be assumed to be the same duration, there is no need to worry about what the duration actually is. This model is very common in the traditional social networks world. Egocentric survey data may aggregated into a set of weekly network ‘panels’, each of which is thought of as a discrete time step in the evolution of the network. We ignore the exact timing of what minute each survey was completed, so that we can compare the week-to-week dynamics.

5.2 You might be continuous if...

In a ‘continuous’ model, measurements are thought of as taking place at an instantaneous point in time (as precisely as can be reasonably measured). Events can have specific durations, but they will almost never be integers. Instead of being present in week 1 and absent in week 2 a relationship starts on Tuesday at 7:45pm and ends on Friday at 10:01am. Continuous time models are useful when the ordering of events is important. It still may be useful to represent observations in panels, but we must assume that the state of the network could have changed between our observation at noon on Friday of week 1 and noon on Friday of week 2.

Although underlying data model for the `networkDynamic` package is continuous time, discrete time models can easily be represented. But it is important to be clear about what model you are using when interpreting measurements. For example, the `activate.vertex` methods can be called using an `onset=t` and `terminus=t+1` style, or an `at=t` style (which converts internally to `onset=t`, `terminus=t`). Here are several ways of representing the similar time information for an edge lasting two time steps which give different results:

```
> disc <- network.initialize(2)
> disc[1,2]<-1
```

```

> activate.edges(disc,onset=4,terminus=6) # terminus = t+1
> is.active(disc,at=4,e=1)

[1] TRUE

> is.active(disc,at=5,e=1)

[1] TRUE

> is.active(disc,at=6,e=1)

[1] FALSE

> cont <- network.initialize(2)
> cont[1,2]<-1
> activate.edges(cont,onset=4,terminus=5)
> is.active(cont,at=4,e=1)

[1] TRUE

> is.active(cont,at=5,e=1)

[1] FALSE

> cont <- network.initialize(2)
> cont[1,2]<-1
> activate.edges(cont,onset=3.0,terminus=5.0001)
> is.active(cont,at=4,e=1)

[1] TRUE

> is.active(cont,at=5,e=1)

[1] TRUE

> point <- network.initialize(2) # continuous waves
> point[1,2]<-1
> activate.edges(point,at=4)
> activate.edges(point,at=5)
> is.active(point,at=4,e=1)

[1] TRUE

> is.active(point,at=4.5,e=1) # this doesn't makes sense

[1] FALSE

> is.active(point,at=5,e=1)

[1] TRUE

```

6 Show me how it was: extracting static views of dynamic networks

Working with spells correctly can be complex, so the package provides utility methods for dynamic versions of common network operations. View the help page at `?network.extensions` for full details and arguments.

6.1 Testing for activity

As is probably already apparent, the activity range of a vertex, set of vertices, edge, or set of edges can be tested using the `is.active` method.

```
> is.active(triangle, onset=1, length=1, v=2:3)
```

```
[1] TRUE FALSE
```

```
> is.active(triangle, onset=1, length=1, e=get.edgeIDs(triangle, v=1))
```

```
[1] TRUE
```

6.2 Listing active elements

Depending on the end use, a more convenient way to express these queries might be to use utility functions to retrieve the ids of the network elements of interest that are active for that time range.

```
> get.edgeIDs.active(triangle, onset=2, length=1, v=1)
```

```
[1] 1
```

```
> get.neighborhood.active(triangle, onset=2, length=1, v=1)
```

```
[1] 2
```

```
> is.adjacent.active(triangle, vi=1, vj=2, onset=2, length=1)
```

```
[1] TRUE
```

These methods of course accept the same additional arguments as their `network` counterparts.

6.3 Basic descriptives

In some contexts, especially writing simulations on a network that can work in both discrete and continuous time, it may be important to know all the time points at which the structure of the network changes. The package includes a function `get.change.times` that can return a list of times for the entire network, or edges and vertices independently:

```

> get.change.times(triangle)

[1] 1 2 3 4 5 6 10

> get.change.times(triangle,vertex.activity=FALSE)

[1] 1 2 3 4 6

> get.change.times(triangle,edge.activity=FALSE)

[1] 1 4 5 10

```

We have also implemented dynamic versions of the basic network functions `network.size` and `network.edgcount` which accept the standard activity parameters:

```

> network.size.active(triangle,onset=2,terminus=3)

[1] 2

> network.edgcount.active(triangle,at=5)

[1] 1

```

6.4 Wiping the slate: removing activity information

Most `network` methods will ignore the timing information on a `networkDynamic` object. However, there may be situations where it is desirable to remove all of the timing information attached to a `networkDynamic` object. (Note: this is not the same thing as deactivating elements of the network.) This can be done using the `delete.edge.activity` and `delete.vertex.activity` functions which do accept arguments to specify which elements should have the timing information deleted.

```

> delete.edge.activity(triangle)
> delete.vertex.activity(triangle)
> get.change.times(triangle)

numeric(0)

```

Although the timing information of the edges and/or vertices may be removed, other `networkDynamic` methods will assume activity or inactivity across all time points, based on the argument `active.default`.

6.5 Differences between ‘any’ and ‘all’ aggregation rules

In addition to the point-based (`at` syntax) or unit interval (`length=1`) activity tests and extraction operations used in most examples so far, the methods also support the idea of a ‘query spell’ specified using the same onset and terminus syntax. So it is also possible (assuming it makes sense for the network being studied) to use `length=27.52` or `onset=0, terminus=256`. Querying with a time range does raise an issue: how should we handle situations where edges or vertices have spells that begin or end part way through the query spell? Although other potential rules have been proposed, the methods currently include a `rule` argument that can take the values of `any` (the default) or `all`. The former returns elements if they are active for any part of the query spell, and the later only returns elements if they are active for the entire range of the query spell.

```
> query <- network.initialize(2)
> query[1,2] <-1
> activate.edges(query, onset=1, terminus=2)
> is.active(query,onset=1,terminus=2,e=1)

[1] TRUE

> is.active(query,onset=1,terminus=3,rule='all',e=1)

[1] FALSE

> is.active(query,onset=1,terminus=3,rule='any',e=1)

[1] TRUE
```

7 Dynamic attributes: the next frontier

Clearly an essential feature of dynamic networks is the ability to express time-varying attributes for networks, vertices (changing properties) and edges (changing weights). The authors of this package have completed a specification and draft implementation of dynamic attributes, and will include dynamic attribute features and utility methods in an upcoming release of `networkDynamic`.

8 Other Coming Attractions

`ndtv`: Network Dynamic Temporal Visualization package – like TV for your networks. The `ndtv` package creates network animations of dynamic networks stored in the `networkDynamic` format. Provides the tools developed in (?) but with R methods for building, controlling, and rendering out animations.

9 Vocabulary definitions

This is a list of terms and common function arguments giving their special meanings within the context of the **networkDynamic** package.

spell bounded interval of time describing activity period of a network element

onset beginning of spell

terminus end of a spell

length the duration of a spell

at a single time point, a spell with zero length where onset=terminus

start beginning (least time) of observation period (or series of spells)

end end (greatest time) of observation period (or series of spells)

spell list or spell matrix a means of describing the activity of a network or network element using a matrix in which one column contains the onsets and another the termini of each spell

toggle list a means of describing the activity of a network or network element using a list of times at which an element changed state ('toggled')

onset-censored when elements of a dynamic network are known to be active before start of the defined observation period, even if the onset of the spell is not known.

terminus-censored when elements of a dynamic network are known to be active after the end of the defined observation period, even if the terminus of the spell is not known.

10 Complete package function listing

Below is a reference list of all the public functions included in the package **networkDynamic**

```
> cat(ls("package:networkDynamic"),sep="\n")
```

```
activate.edges  
activate.vertices  
add.edges.active  
add.vertices.active  
as.data.frame.networkDynamic  
as.networkDynamic  
deactivate.edges  
deactivate.vertices  
delete.edge.activity
```

```

delete.vertex.activity
get.change.times
get.edge.activity
get.edgeIDs.active
get.edges.active
get.neighborhood.active
get.vertex.activity
is.active
is.adjacent.active
is.networkDynamic
network.dyadcount.active
networkDynamic
network.dynamic.check
network.edgcount.active
network.extract
network.naedgecount.active
network.size.active
print.networkDynamic
%%

```
